Goal

Stima della partizione e grafo con bulky functions 2024.

Simulated data

Simuliamo i dati in `sim_data.R` con $p=20$ basi e 3 cluster di dimensioni $[6,6,8]$. Grafo e matrice di precisione sono generati attraverso la funzione `Generate_BlockDiagonal`.

```
# Import simulated data
BaseMat = as.matrix(read_csv('simulated_data20/BaseMat.csv'))      # matrix Phi, dim = 200 x 20
y_hat_true = as.matrix(read_csv('simulated_data20/y_hat_true.csv')) # y true, dim = 300 x 200
beta_true = as.matrix(read_csv('simulated_data20/beta_true.csv'))   # beta, dim = 300 x 20
mu_true = as.matrix(read_csv('simulated_data20/mu_true.csv'))       # mu true, dim = 20 x 1

# object containing the true graph G, the true precision matrix K
simKG <- readRDS("simulated_data20/simKG.rds")

n <- dim(y_hat_true)[1] # n=300
r <- dim(y_hat_true)[2] # r=200
p <- dim(BaseMat)[2]    # p=20
```

Initialization

```
# Define the starting Beta matrix
Beta = matrix(rnorm(n = p*n), nrow = p, ncol = n)

# Define the starting value of mu
mu = rnorm(n=p)

# Fix tau_eps (squared)
tau_eps = 100

# Define the starting precision matrix K and graph G
K = matrix(0,p,p)
G = matrix(0,p,p)

# Define the starting partition
rho = p
z = rep(1,p)

# Compute quantities for function UpdateParamGSL
tbase_base = t(BaseMat)%*%BaseMat      # p x p (phi_t * phi)
tbase_data = t(BaseMat)%*%t(y_hat_true) # p x n (phi_t * Y_t)
